

Looking locally to see globally:

motif sampling to distinguish interaction type and
predict dynamical properties of whole networks

Matthew J. Michalska-Smith

University of Chicago

distinguish interaction type

Gustav Klimt, Mohnfeld

Piet Mondrian, Composition with Grids: Checkerboard Composition with Light Colors

How can we tell where this matrix
has come from?

Why might this be desirable/interesting?

- ▶ Insights into mechanisms of network formation
- ▶ Unknown/ambiguous interactions

Why might this be possible?

- ▶ Observed differences (*sensu* Thébault & Fontaine, Science, 2010)
- ▶ Different reactions/coevolutions to mutualistic vs antagonistic interactions

Data

- ▶ 323 **Bipartite** Networks
 - ▶ 3-21977 rows
 - ▶ 2-888 columns
 - ▶ 0.008-0.93 connectance
- ▶ Subdivided into 4 types, 14 subtypes

| Antagonism | Mutualism | Biogeography | Non-biological |
|-----------------|----------------------|-------------------|--------------------|
| Bacteria-Phage | Ant-Plant | Species-Islands | Awards-Recipients |
| Host-Parasitoid | Plant-Seed Disperser | Species-Mountains | Participant-Answer |
| Host-Parasite | Plant-Pollinator | OTU-Body Site | Cultural Evolution |
| Plant-Herbivore | Anemone-Fish | | |

Methods: Measuring network properties

36 nonindependent metrics for each network

- ▶ Number of rows, columns, edges, connectance
- ▶ Leading eigenvalues
- ▶ Gaps between leading eigenvalues
- ▶ Traces of matrix powers
- ▶ Subgraph (motif) counts
- ▶ Nestedness
- ▶ Modularity

Methods: Controlling for unreliable variation

Randomized Networks

- ▶ Erdős-Rényi
 - Preserves **average** number of interactions/species
- ▶ Configuration
 - Preserves **actual** number of connections/species

Normalization

- ▶ p-value

$$\frac{\text{Number of random networks with Value} < \text{Observed Value}}{\text{Number of randomizations}}$$

- ▶ z-score

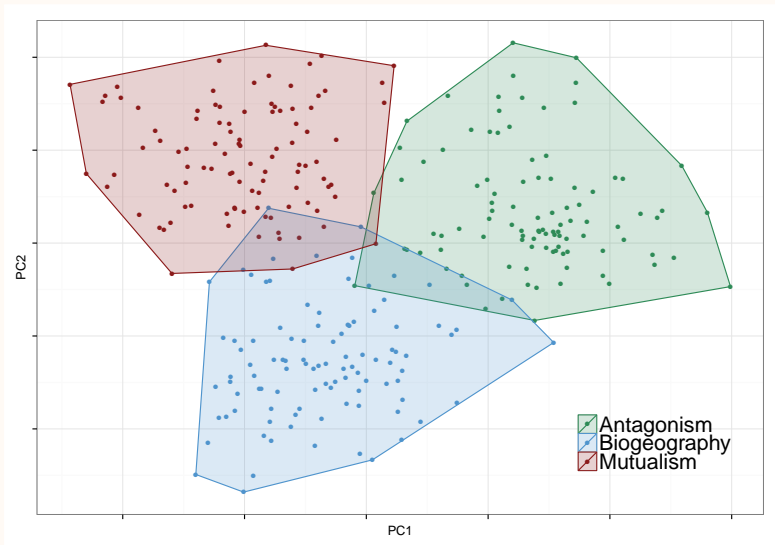

$$\frac{\text{Observed value} - \text{Mean of random network values}}{\text{Standard deviation of random values}}$$

Principal Component Analysis

Desired results

Desired results

P-Values

P-Values

Z-Scores

Z-Scores

Significantly Over/Under

Significantly Over/Under

What went wrong?

Insufficient Power?

- ▶ More data
- ▶ More metrics

Improper normalization?

- ▶ Conserve subgraph distributions

Low resolution?

What if nothing went wrong?

Variation within network types/subtypes is greater than variance between them

(Biological) networks are more similar than we thought

The processes which we invoked to form our expectation are not (as) important to network structure

Take-Home Message

There is no silver bullet

- ▶ Biological networks are hard to disentangle using network structure
- ▶ Further exploration is needed to identify which (if any) structural properties are important in delineating different types of biological networks

thank you

CHICAGO

What about “known” differences?
